

The Entity-Relationship (E-R) model

Lecture topics:

- basic E-R modelling
- extensions to E-R modelling
- designing an E-R schema
- deriving relational schema from E-R diagrams

References:

Overview of E-R model

- used for database (conceptual schema) design
- world/enterprise described in terms of:
 - entities
 - attributes
 - relationships
- visualization: *ER-diagram*
- mature methodology (initially described Chen, 1976)

Basic E-R modelling

- **Entity:** a distinguishable object
- **Entity set:** set of entities of same type
- **E.g.**
 - students currently enrolled
 - flights offered by Air Canada
 - burglaries in Ontario during 1999
- Graphical representation of entity sets:

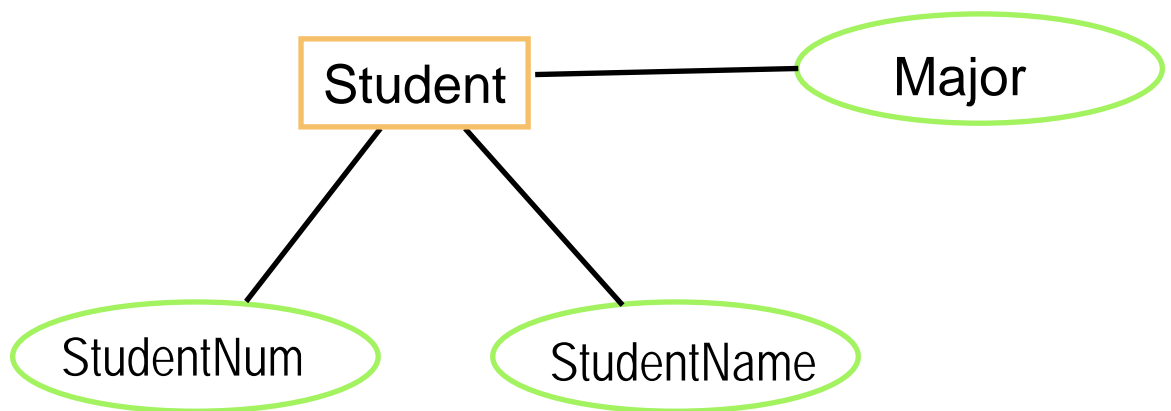

Student

Burglary

Flight

...continued

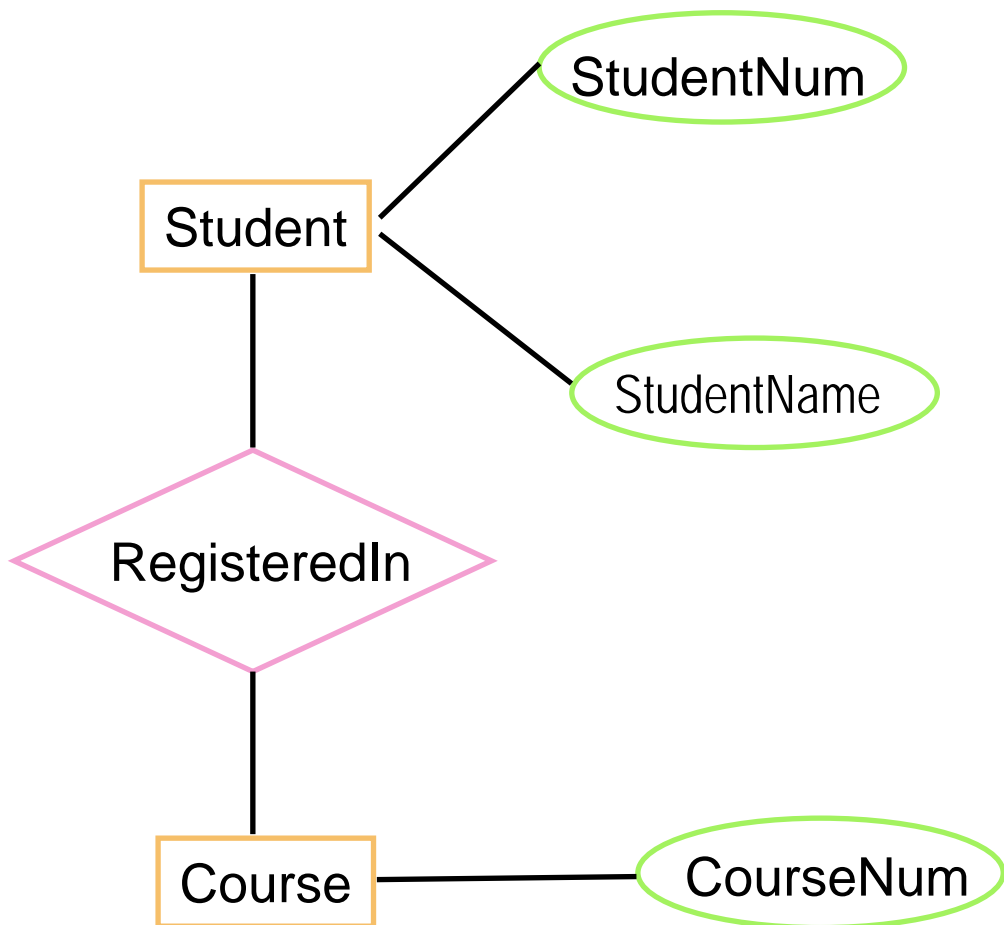

- **Attributes** describe properties of entities
 - **E.g.** for Student entities: StudentNum, StudentName, Major, etc.
- **Domain:** set of permitted values for an attribute
- Graphical representation of attributes:

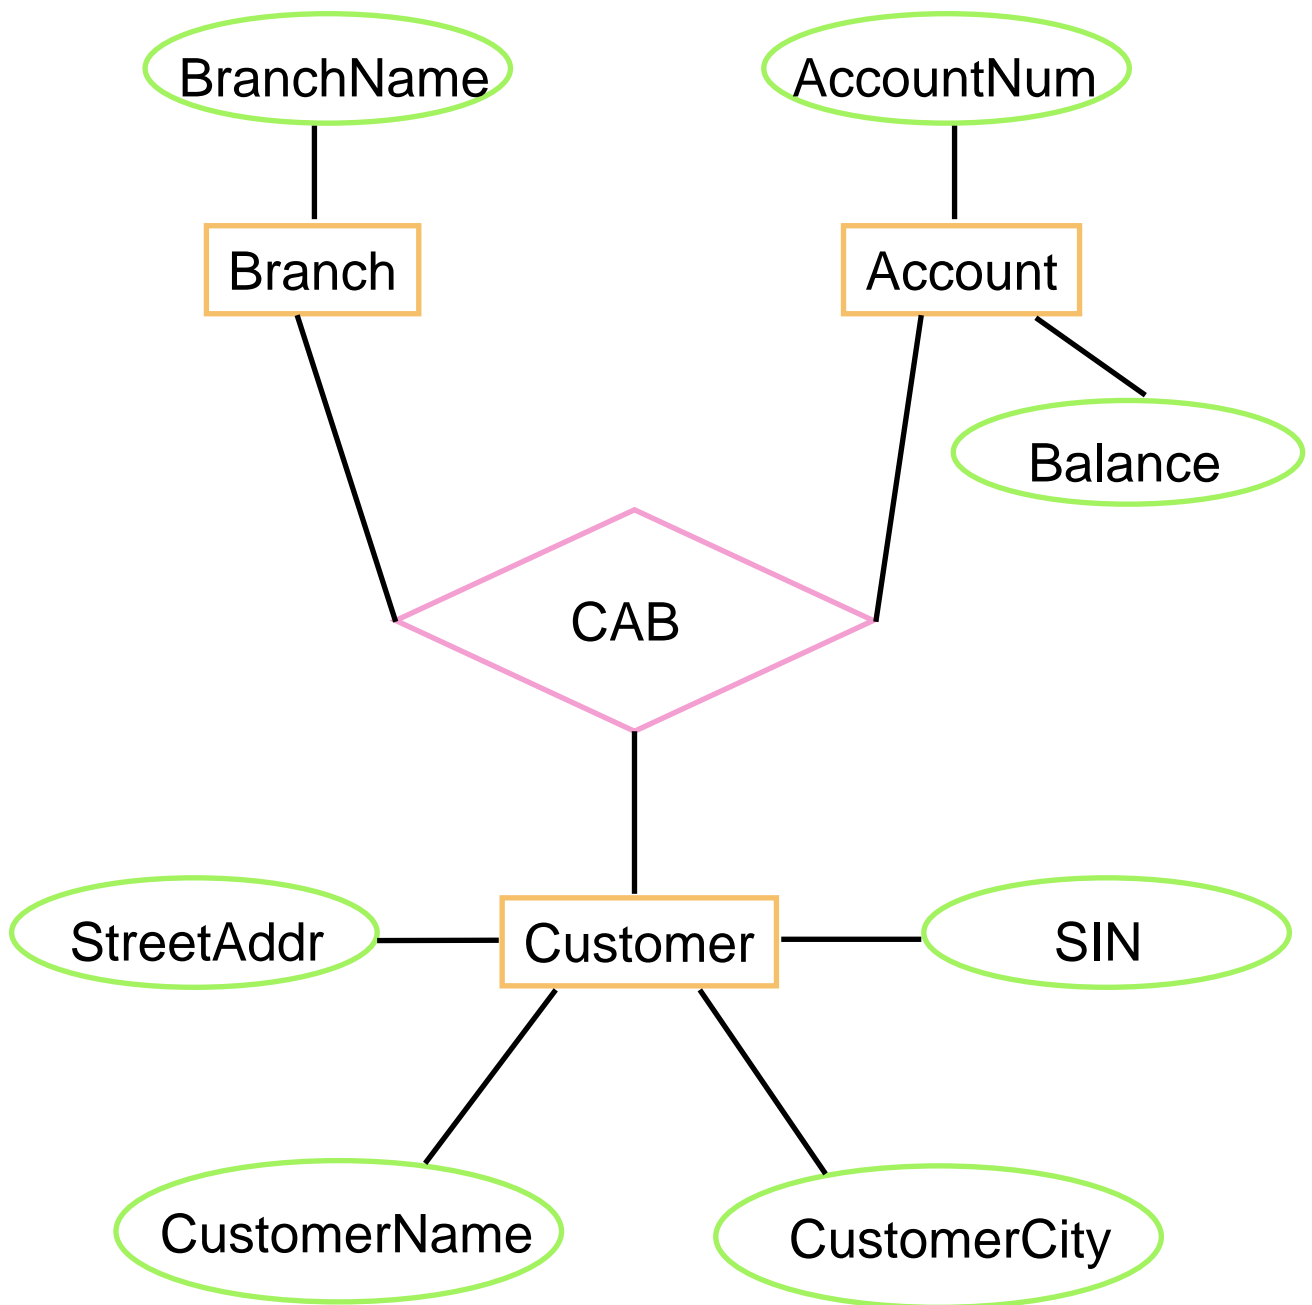

...continued

- **Relationship:** representation of the fact that certain entities are related to each other
- **Relationship set:** set of relationships of a given type
- **E.g.**
 - students registered in courses
 - passengers booked on flights
 - parents and their children
 - bank branches, customers, and their accounts
- In order for a relationship to exist, the participating entities must exist

Graphical representation of relationship sets

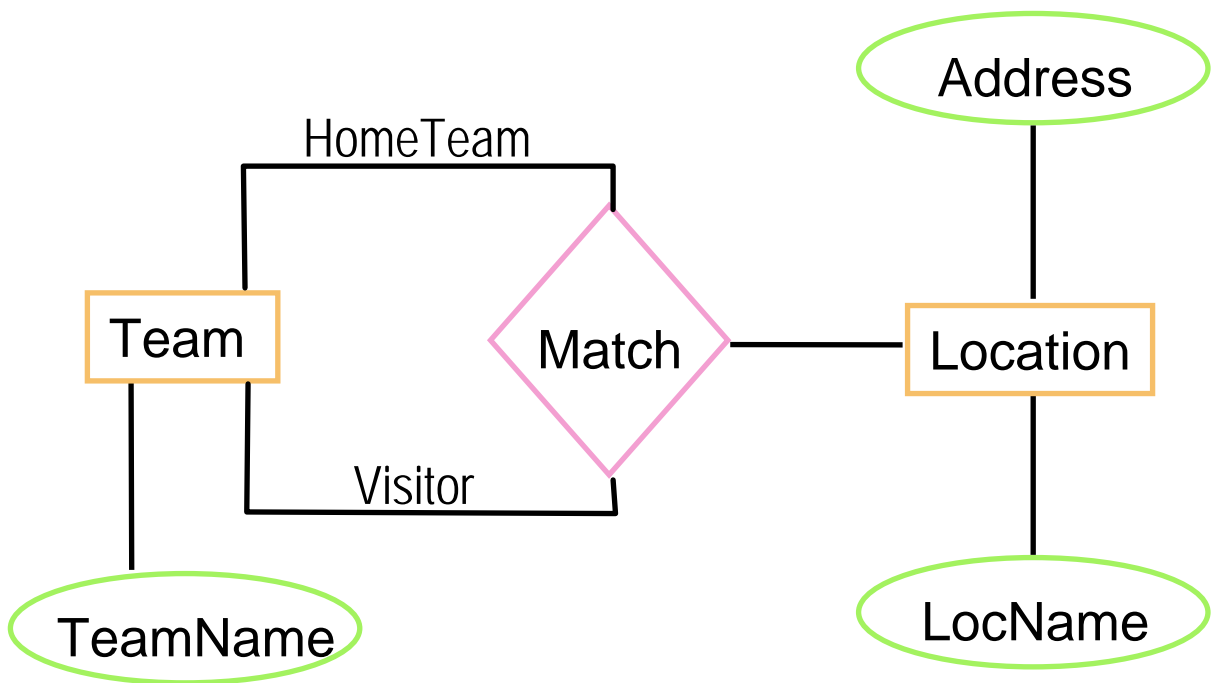

...continued

Recursive relationships and role names

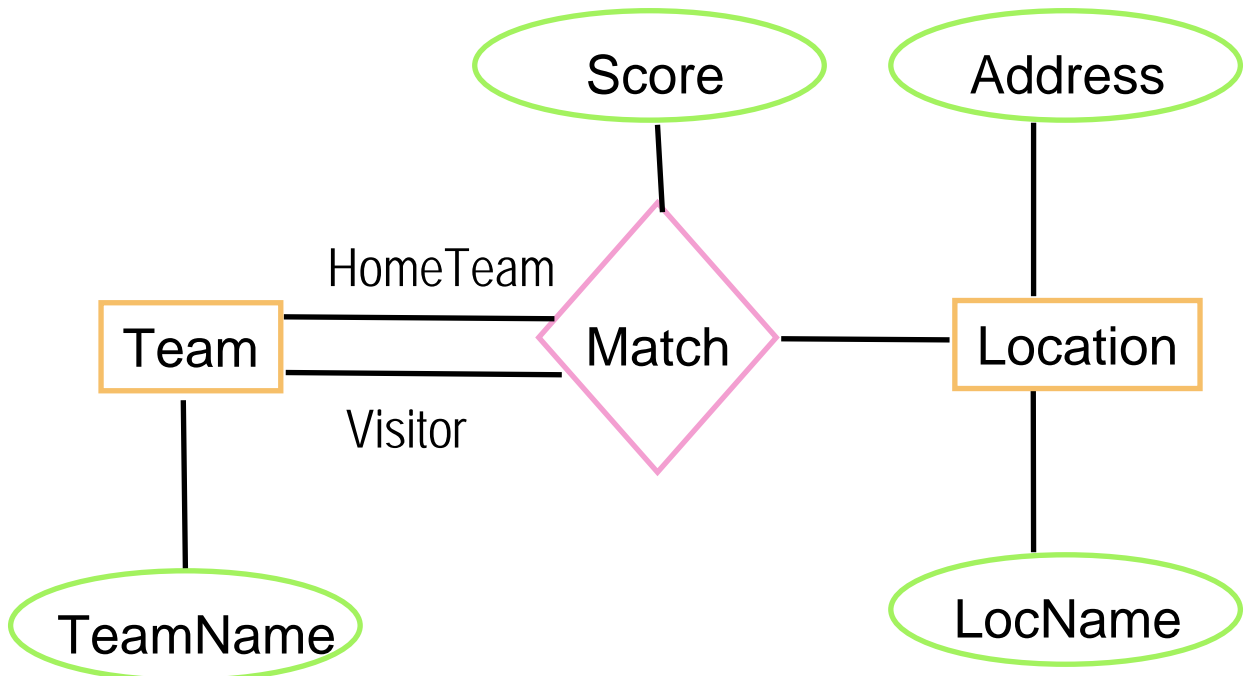

- **Role:** the function of an entity set in a relationship set
- **Role name:** an explicit indication of a role
- **E.g.**

- Role labels are needed whenever an entity set has multiple functions in a relationship set.

Relationships and attributes

- Relationships may also have attributes:

Constraints in E-R models

- binary relationship cardinalities
- general cardinality constraints
- primary keys
- existence dependencies

Binary relationship cardinality

- relationships between two entity sets, A and B
- many-to-one (N:1):** each entity in A can be related to at most one entity in B, but an entity in B may be related to many entities in A
- E-R diagram notation:

- E.g.**

- similarly: **one-to-many (1:N)**

...continued

- **one-to-one (1:1):** each entity in A can be related to at most one entity in B, and vice versa
- **E.g.**

- **many-to-many (N:N):** an entity can be related to many entities in the other set, and vice versa
- **E.g.**

General cardinality constraints

- Determine lower and upper bounds on the number of relationships of a given relationship set in which a component entity may participate
- E-R diagram notation:

- **E.g.**

Primary keys

- as in relational model, each entity must be distinguishable from any other entity in its set by its attributes
- **Primary key:** selection of attributes chosen by designer as a primary identifier of entities in entity set
- **E.g.**

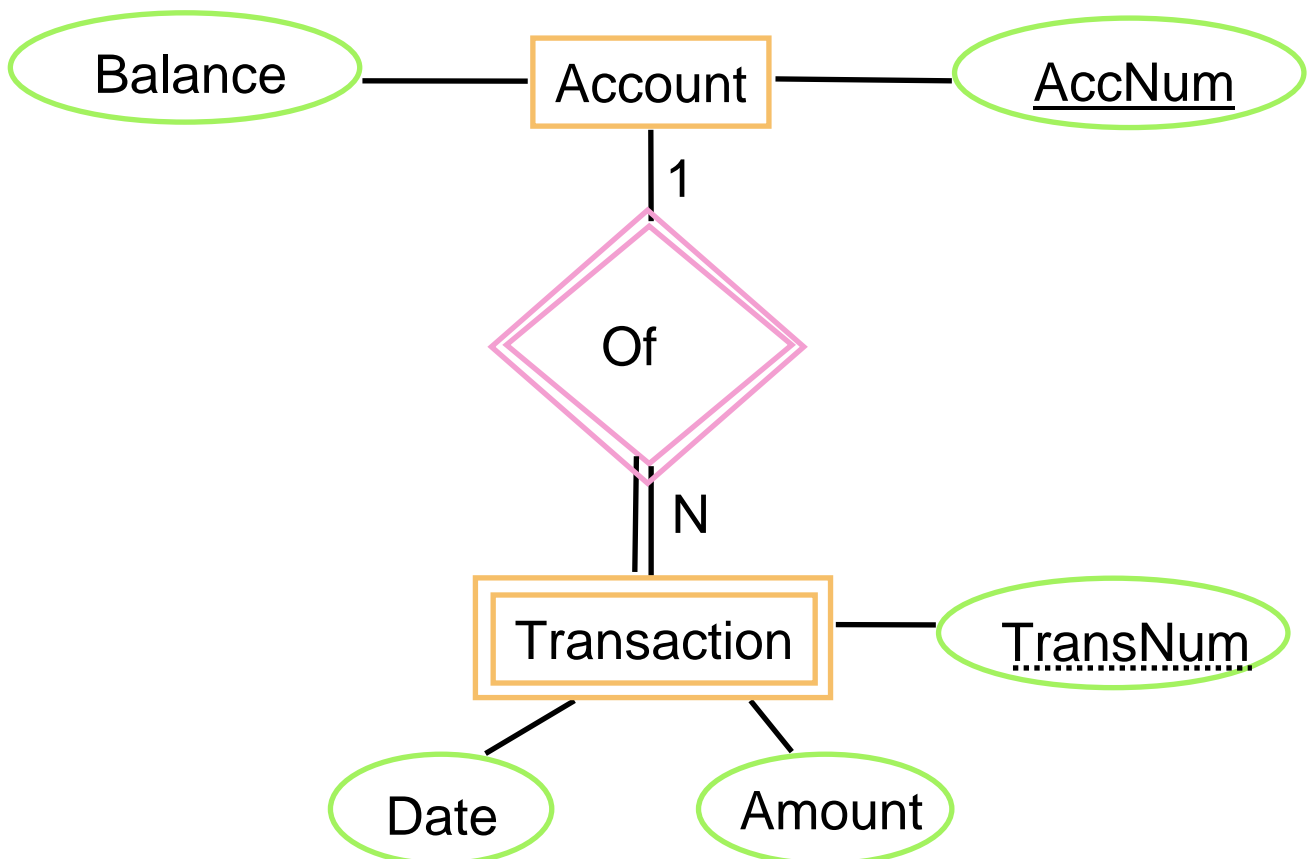

- **E.g.**

Existence dependencies

- Sometimes the existence of an entity depends on the existence of another entity
- If x is **existence dependent** on y , then
 - y is a **dominant entity**
 - x is a **subordinate entity**
- **E.g.** “Transactions are existence dependent on accounts.”

Primary keys of subordinate entity sets

- **Weak entity set:** an entity set with subordinate entities
- **Strong entity set:** an entity set with no subordinate entities
- primary identifier of weak entity sets combines with primary identifier of associated strong entity set
- **E.g.** “All transactions *for a given account* have a unique transaction number.”

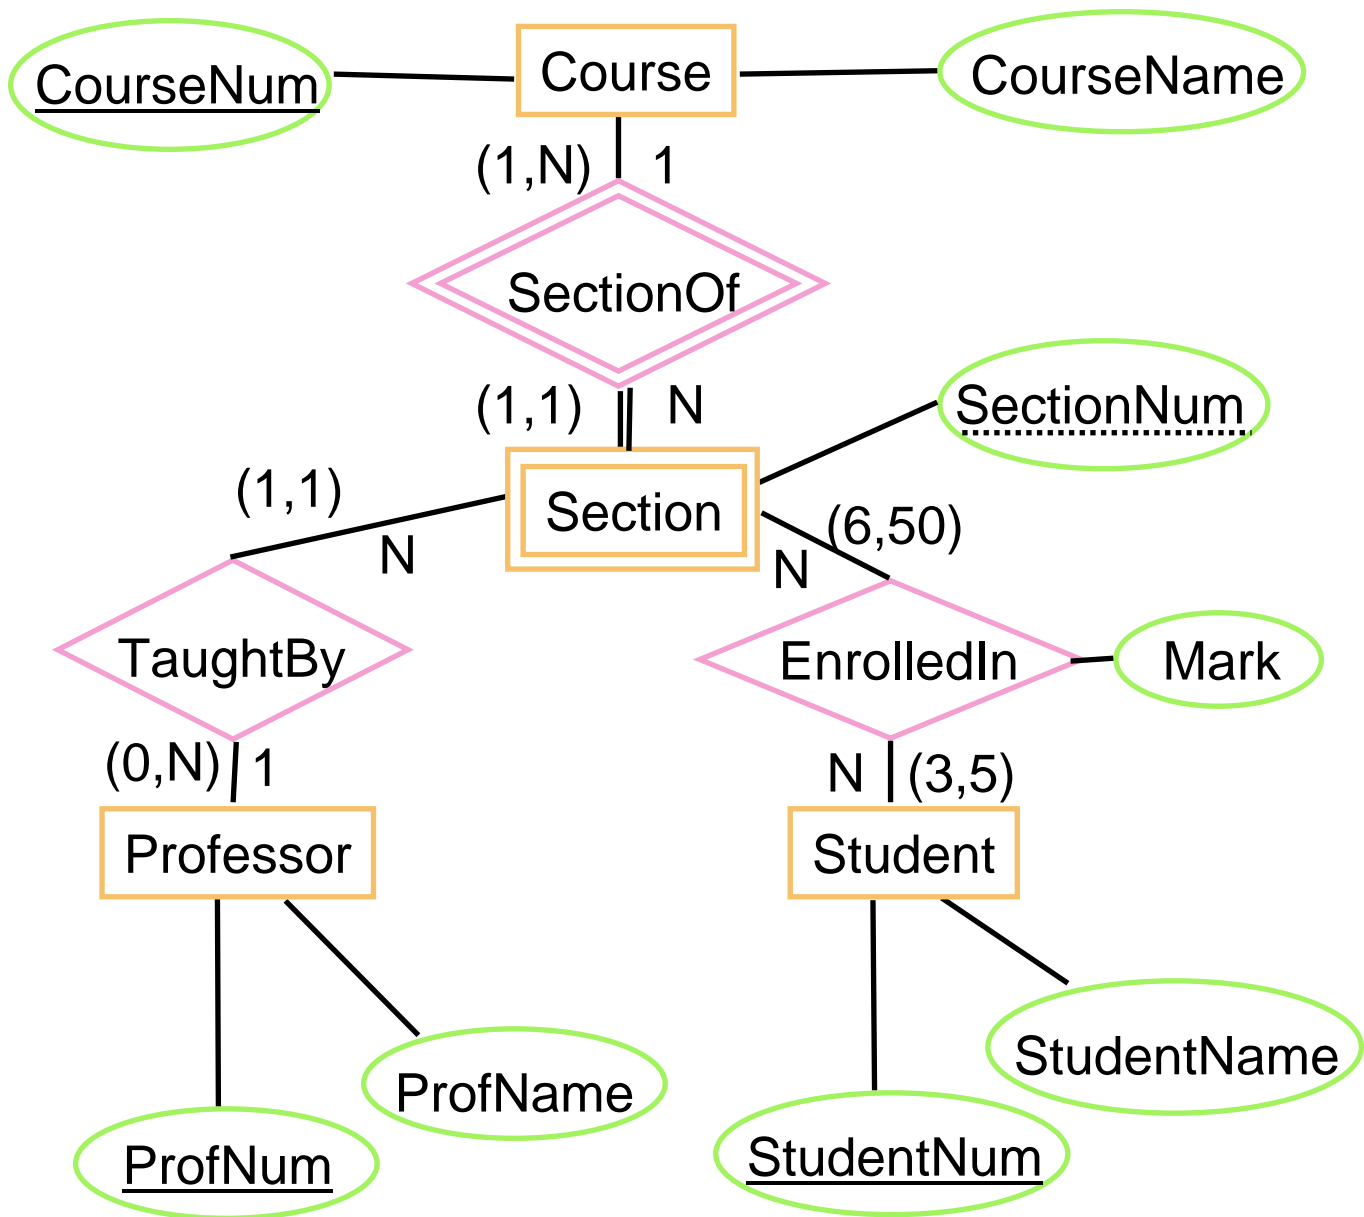

...continued

- A weak entity must have an N:1 relationship to a distinct entity set
- **Discriminator** of a weak entity set: set of attributes that distinguish subordinate entities of the set, for a particular dominant entity
- Primary key for a weak entity set: discriminator + primary key of entity set for dominating entities
- ER diagram notation: (distinguishing an identifying relationship)

Example E-R diagram

Extensions to E-R modeling

- Structured attributes
- Aggregation
- Specialization
- Generalization

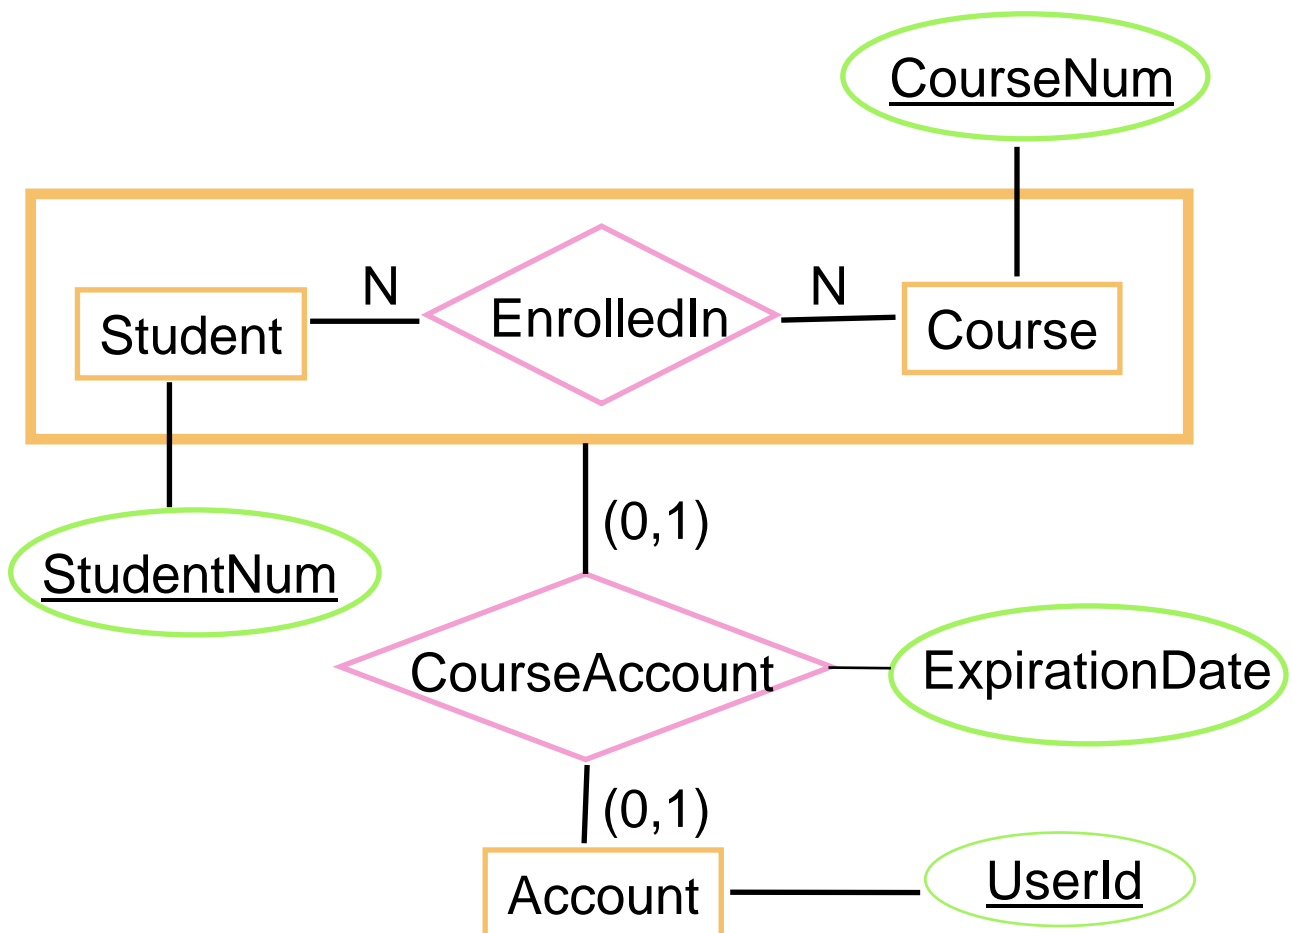

Structured attributes

- **Composite attributes:** attributes composed of two or more other attributes
- **Multi-valued attributes:** attributes that are set-valued
- **E.g.**

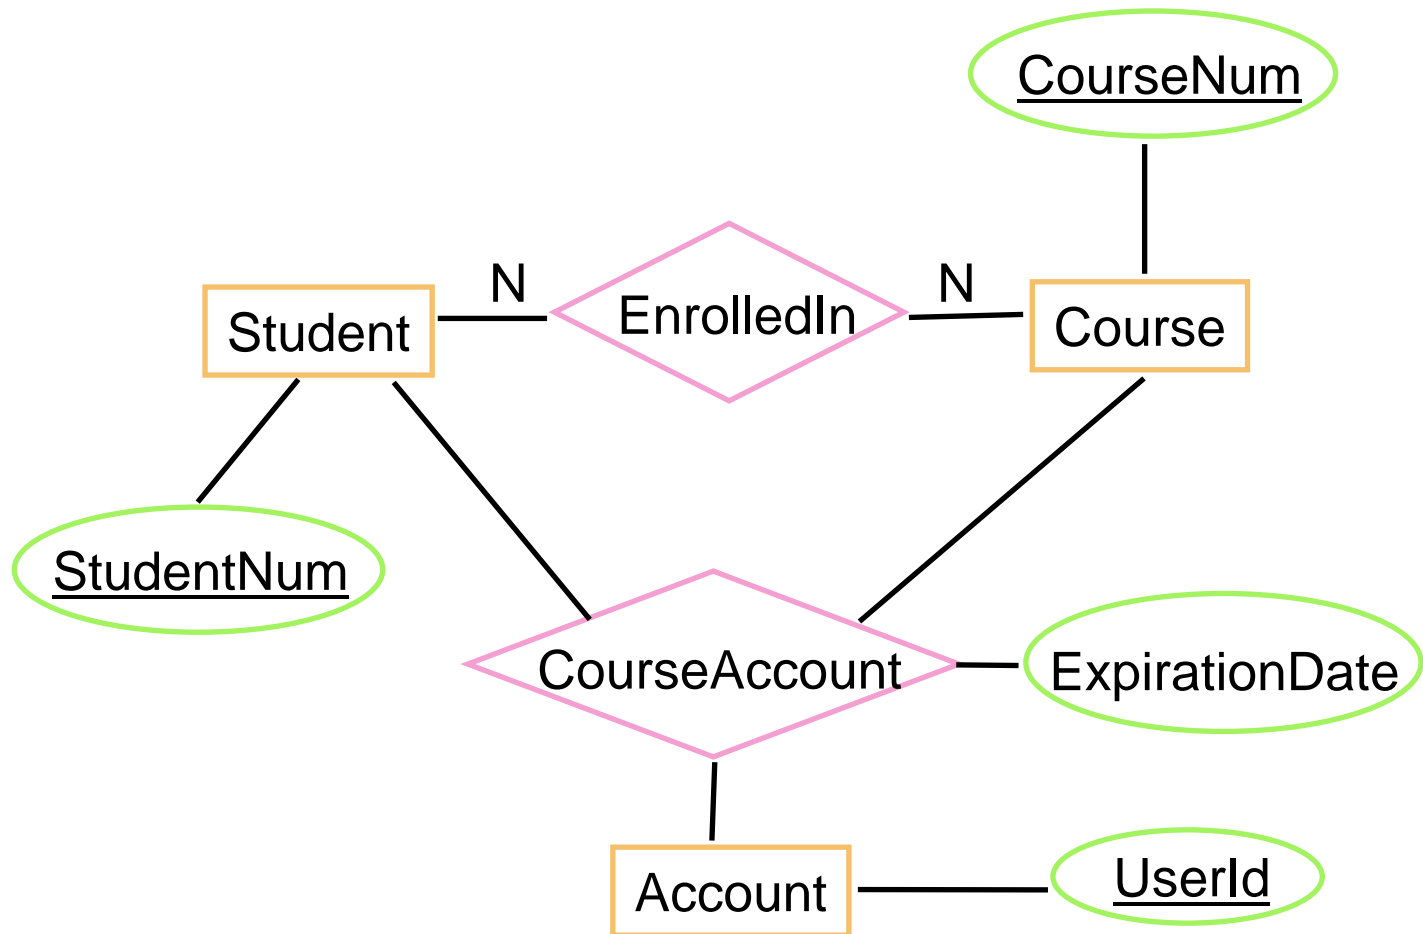

Aggregation

- Relationships can be viewed as higher-level entities
- E.g.** “Accounts are assigned to a given student enrollment.”

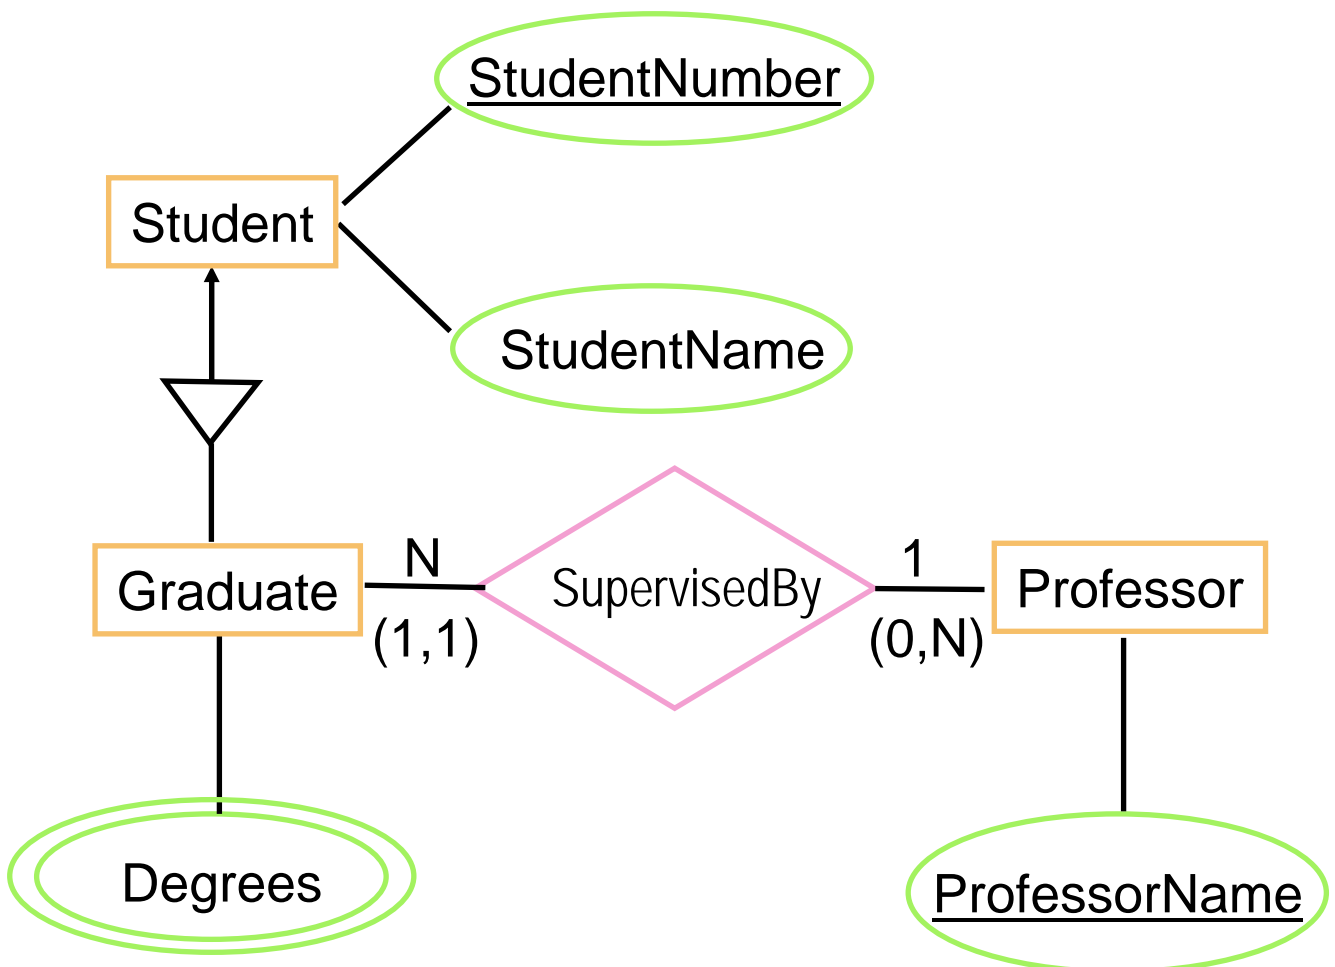

...continued

- same, without aggregation:

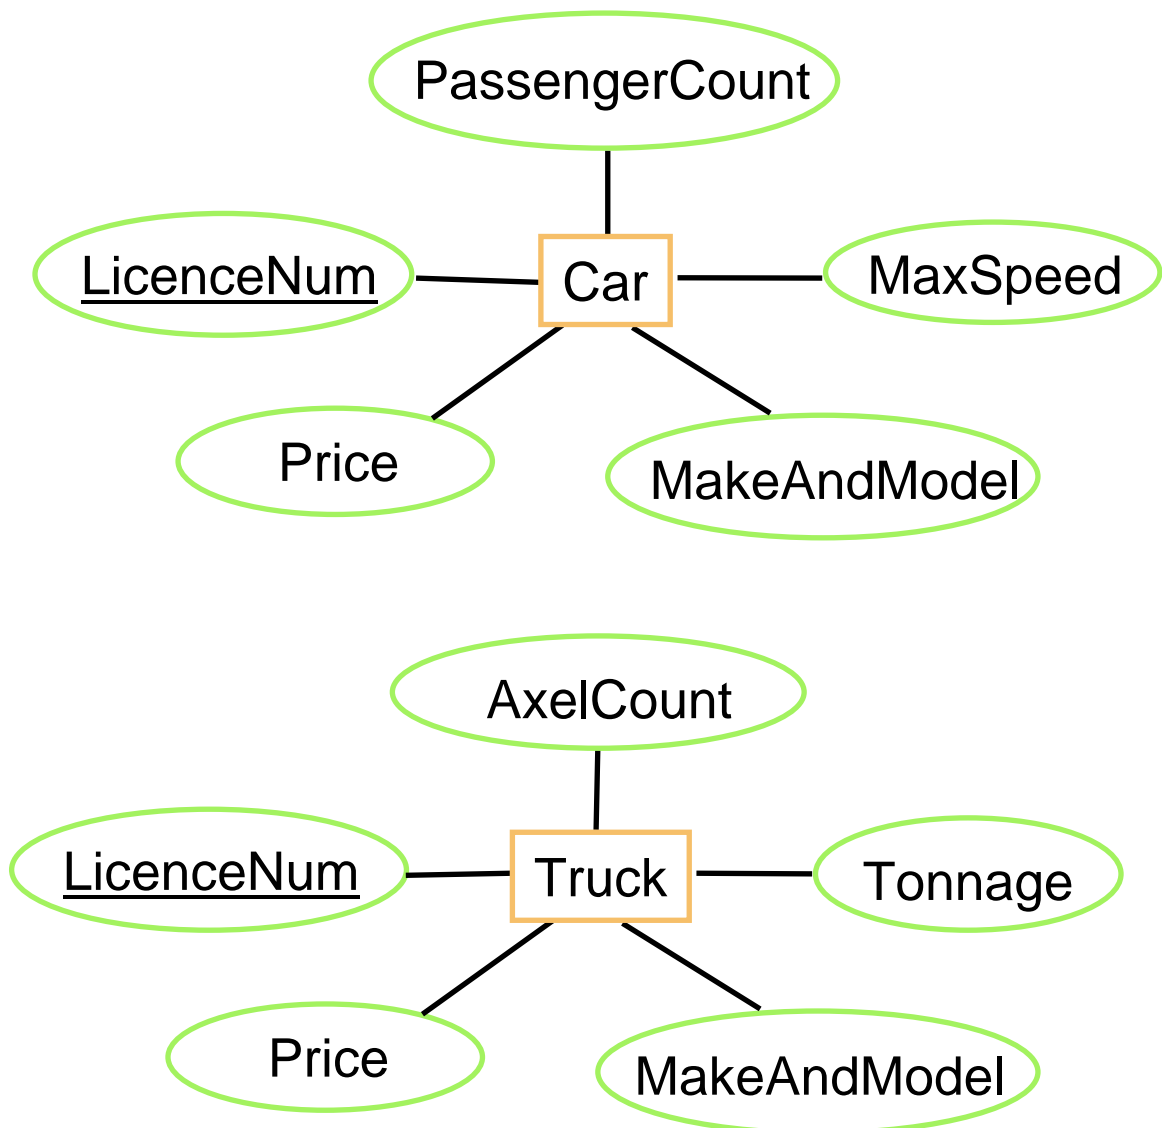

Specialization

- A more specialized kind of entity set may be derived from a given entity set
- **E.g.** “Graduate students are students that have a supervisor and a number of degrees.”

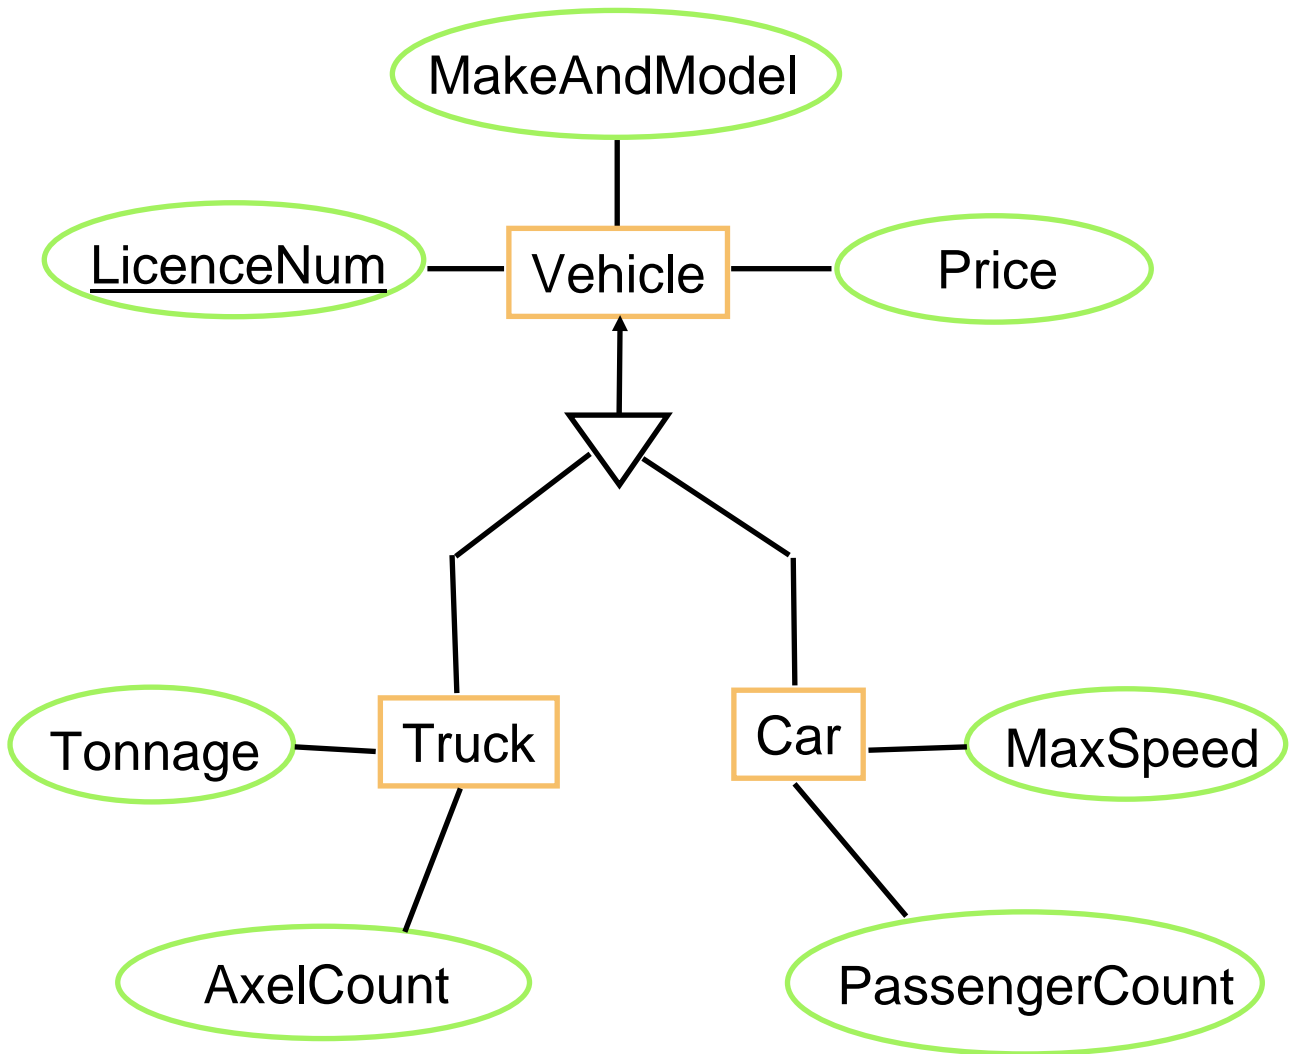

Generalization

- Two or more existing entity sets can be abstracted as a more general kind of entity set
- **E.g.** “A vehicle abstracts the notion of a car and a truck.”

...continued

- alternate diagram notations:

Designing an E-R schema

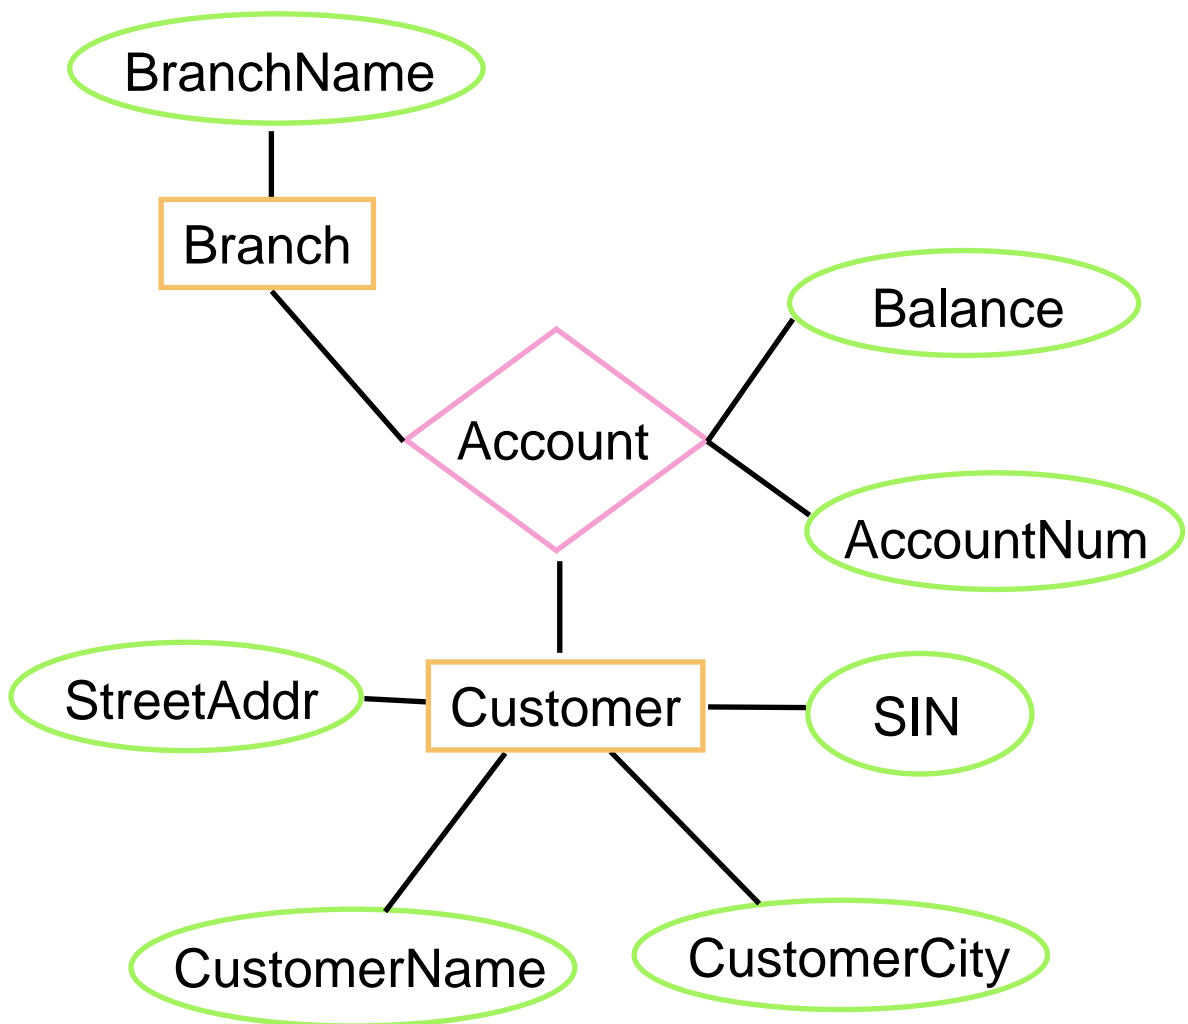

- usually many ways to design an E-R schema
- points to consider:
 - use attribute or entity set?
 - use entity set or relationship set?
 - degrees of relationships?
 - extended features?

Choosing between attributes and entity sets

- no simple answer!
- **E.g.** model employees' phones by a PhoneNumber attribute, or by Phone entity set related to Employee entity set?
 - is it (could it be) a separate object?
 - do we maintain information about it?
 - can several of its kind belong to another single entity?
 - does it make sense to delete such an object?
 - can it be missing from some of the entity set's entities?
 - can it be shared by different entities?
- “yes” to any of the above implies introducing a new entity set

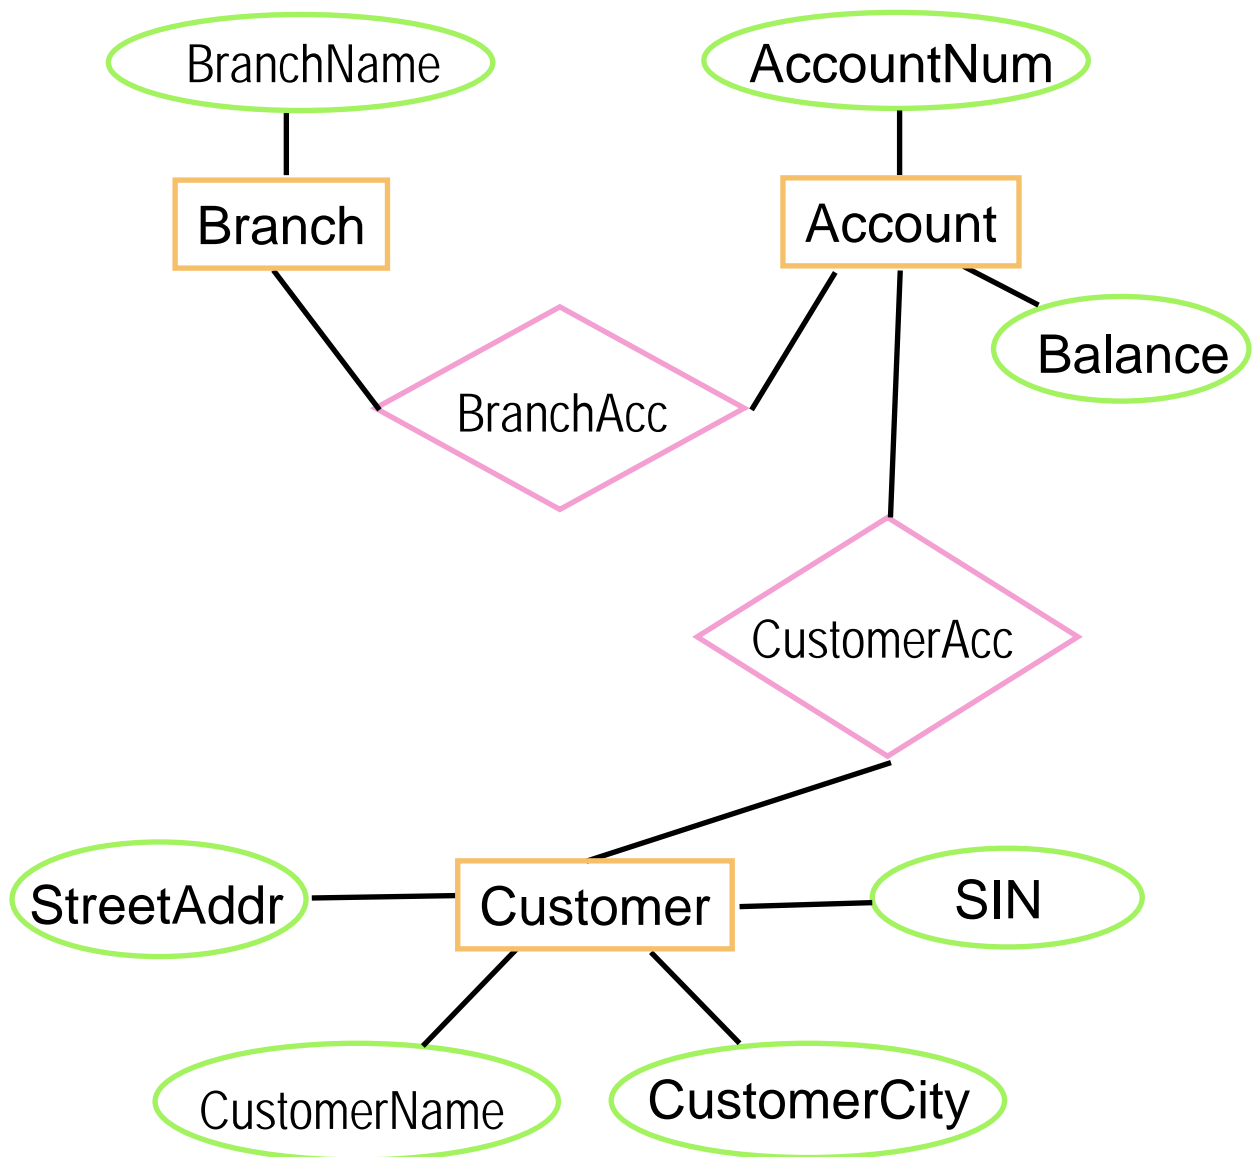

Choosing between entity sets and relationship sets

- again no simple answer!
- **E.g.** Instead of representing accounts as entities, we could represent them as relationships

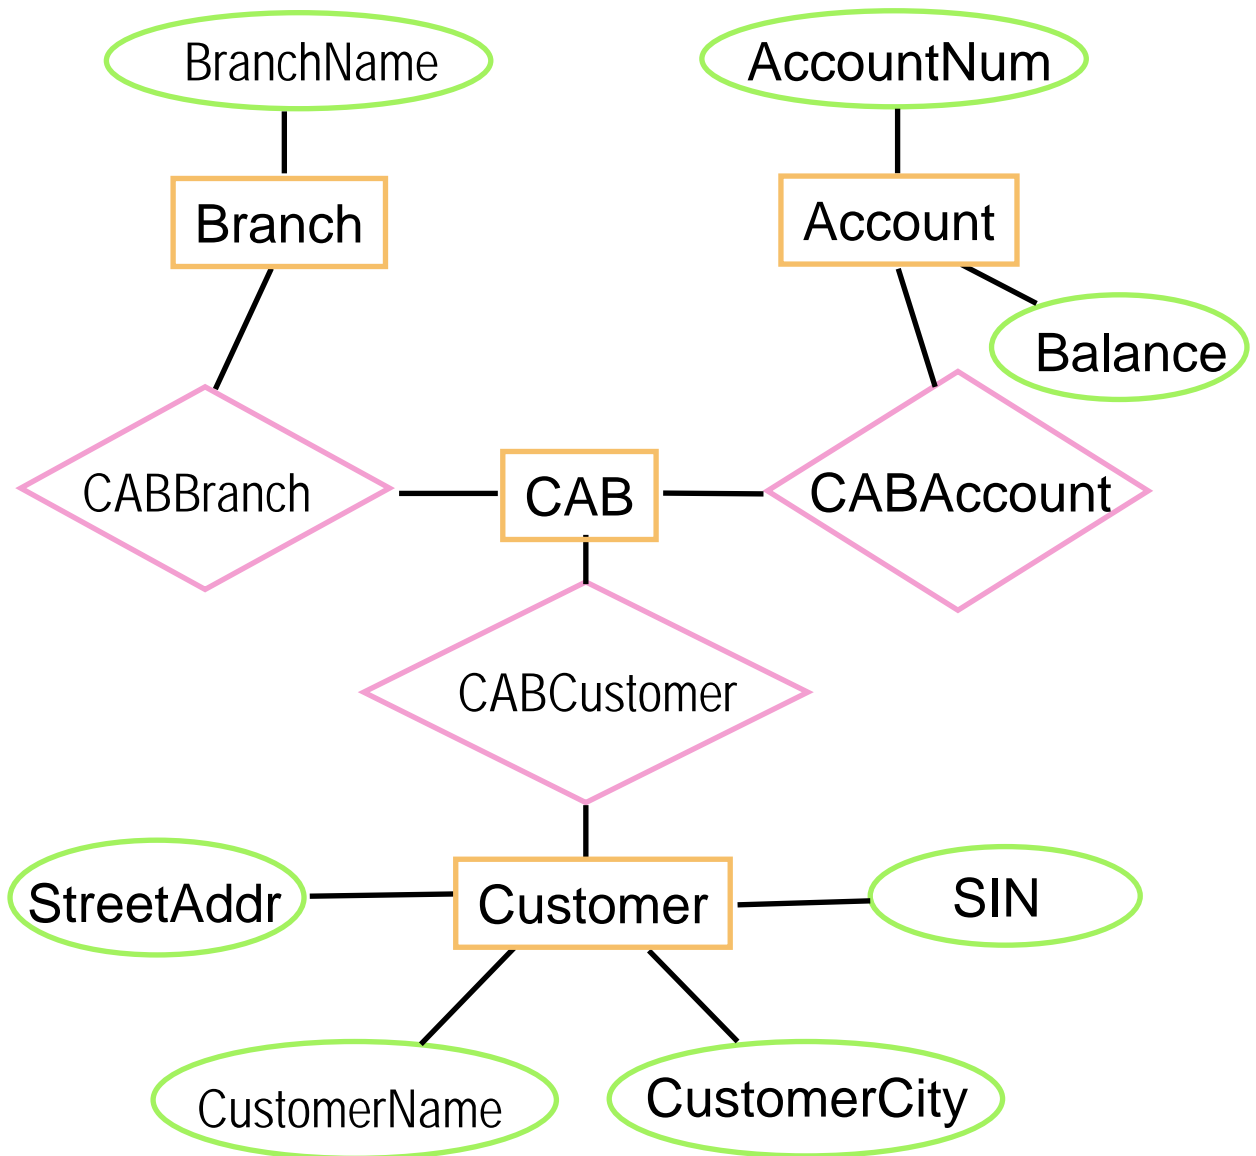

Use of non-binary relationships

- Can always represent a relationship on n entity sets with $n-1$ binary relationships

...continued

- Another representation:

Use of extended E-R features

- Can improve modularity and abstraction if used with care
- Excessive use can complicate design

A simple methodology

- recognize entity sets
- recognize relationship sets and participating entity sets
- recognize attributes of entity sets and attributes of relationship sets
- define binary relationship types and existence dependencies
- define general cardinality constraints, keys and discriminators
- draw diagram

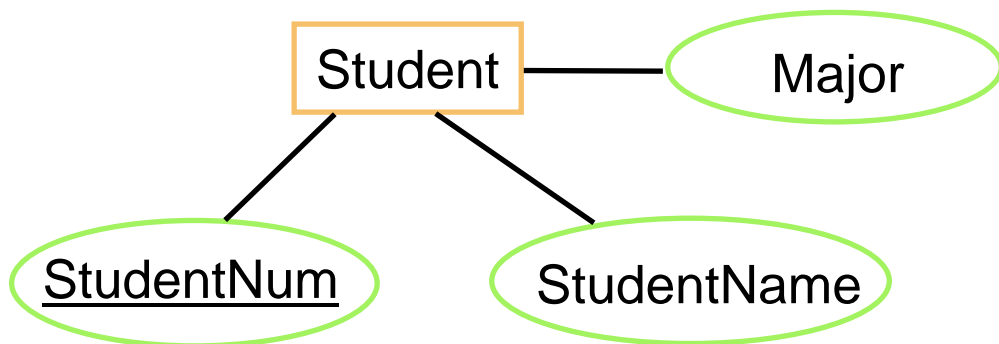

For each step, maintain a log of assumptions motivating the choices, and of restrictions imposed by the choices.

Translating E-R diagrams to relational schema

- General approach is straightforward:
 - each entity set becomes a table
 - each attribute (of an entity) becomes a table column
 - each relationship set becomes either table columns or table by itself

Representing strong entity sets

- Entity set E with attributes a_1, \dots, a_n
→ table E with attributes a_1, \dots, a_n
- Entity of type $E \leftrightarrow$ row in table E
- Primary key of entity set → primary key of table
- E.g.**

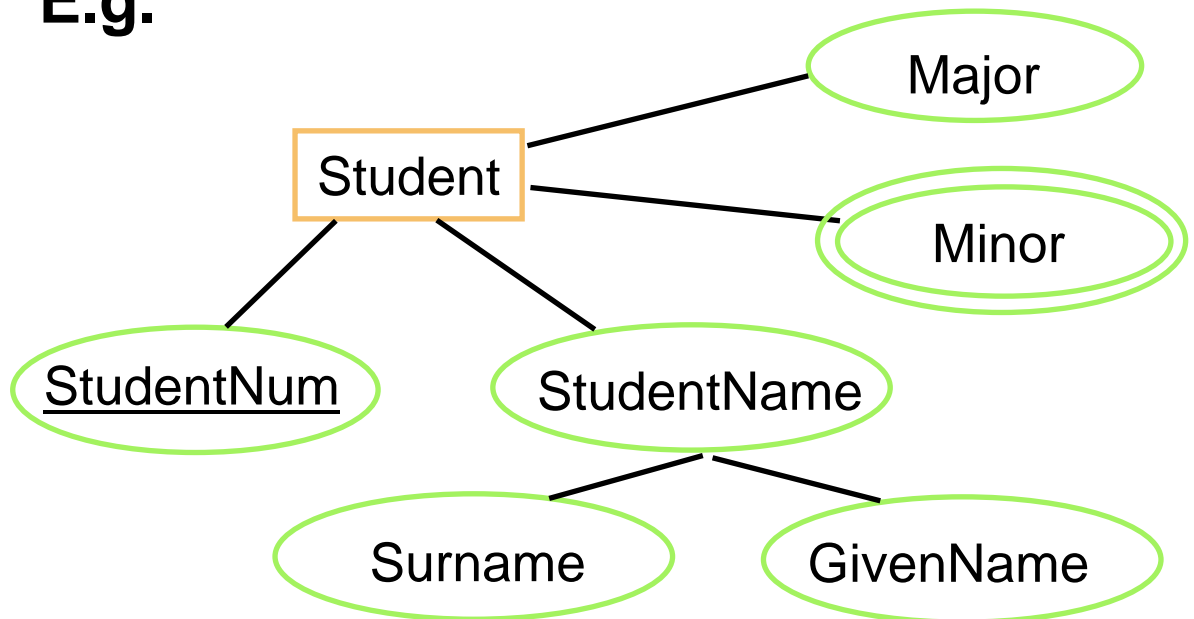

Student

| | | |
|-------------------|-------------|-------|
| <u>StudentNum</u> | StudentName | Major |
|-------------------|-------------|-------|

Structured attributes

- Composite attributes, multi-valued attributes
- **E.g.**

Student

| | | | |
|-------------------|---------|-----------|-------|
| <u>StudentNum</u> | Surname | GivenName | Major |
|-------------------|---------|-----------|-------|

Minors

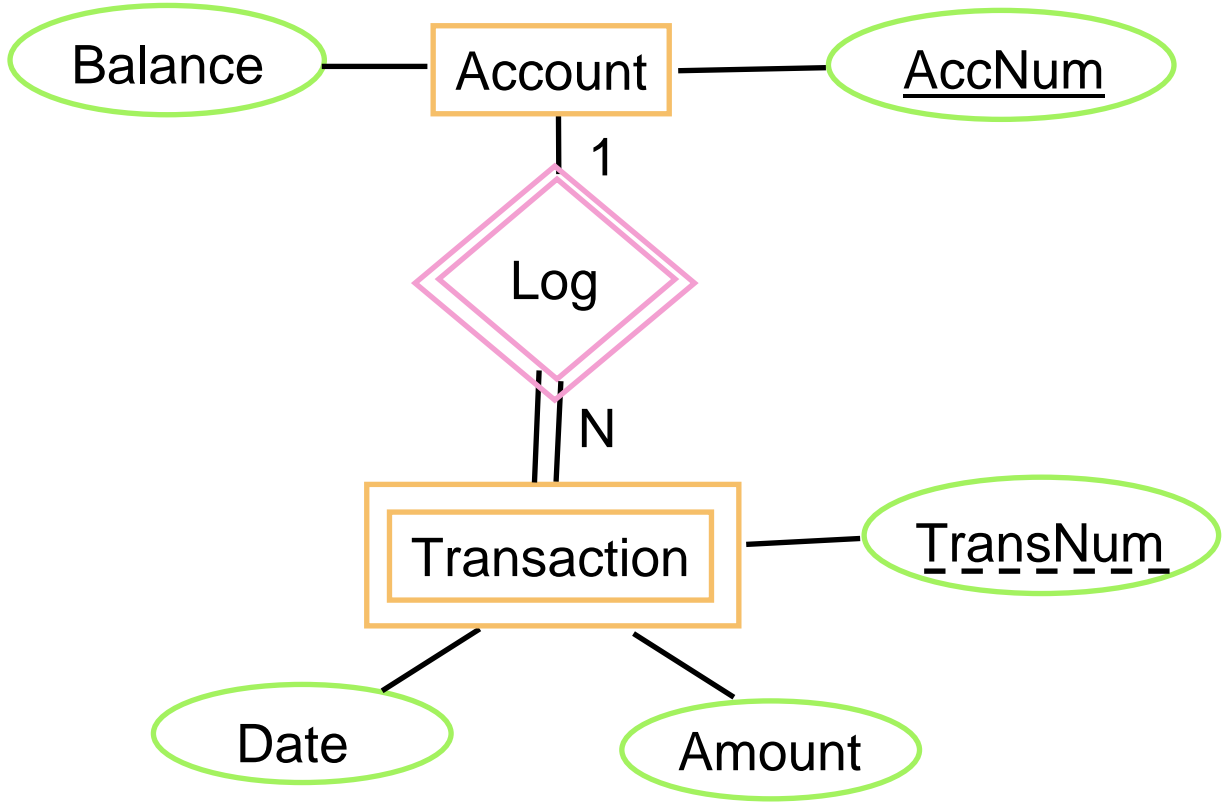

| | |
|-------------------|--------------|
| <u>StudentNum</u> | <u>Minor</u> |
|-------------------|--------------|

Representing Weak Entity Sets

- Weak entity set $E \rightarrow$ table E
- Columns of table E include:
 - attributes of the weak entity set
 - attributes of the identifying relationship set (if any)
 - primary key attributes of entity set for dominating entities
- Primary key of weak entity set
 \rightarrow primary key of table

...continued

- **E.g.**

Account

| | |
|---------------|---------|
| <u>AccNum</u> | Balance |
|---------------|---------|

Transaction

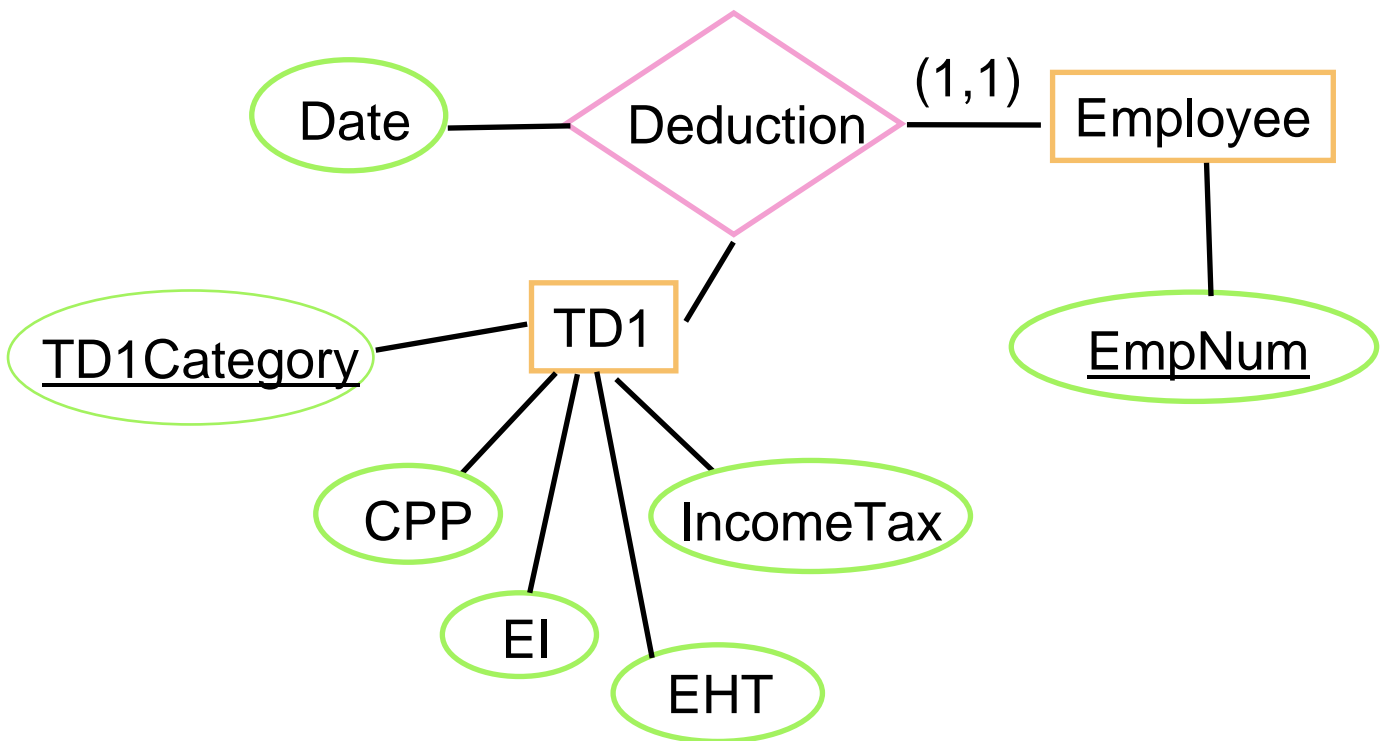

| | | | |
|-----------------|---------------|------|--------|
| <u>TransNum</u> | <u>AccNum</u> | Date | Amount |
|-----------------|---------------|------|--------|

Representing relationship sets

- If the relationship set is an identifying relationship set for a weak entity set then no action needed
- If some component entity set E has general cardinality constraint (1,1), add columns to table E :
 - attributes of the relationship set
 - primary key attributes of remaining component entity sets

...continued

- **E.g.**

Employee

| | | |
|---------------|------|-------------|
| <u>EmpNum</u> | Date | TD1Category |
|---------------|------|-------------|

TD1

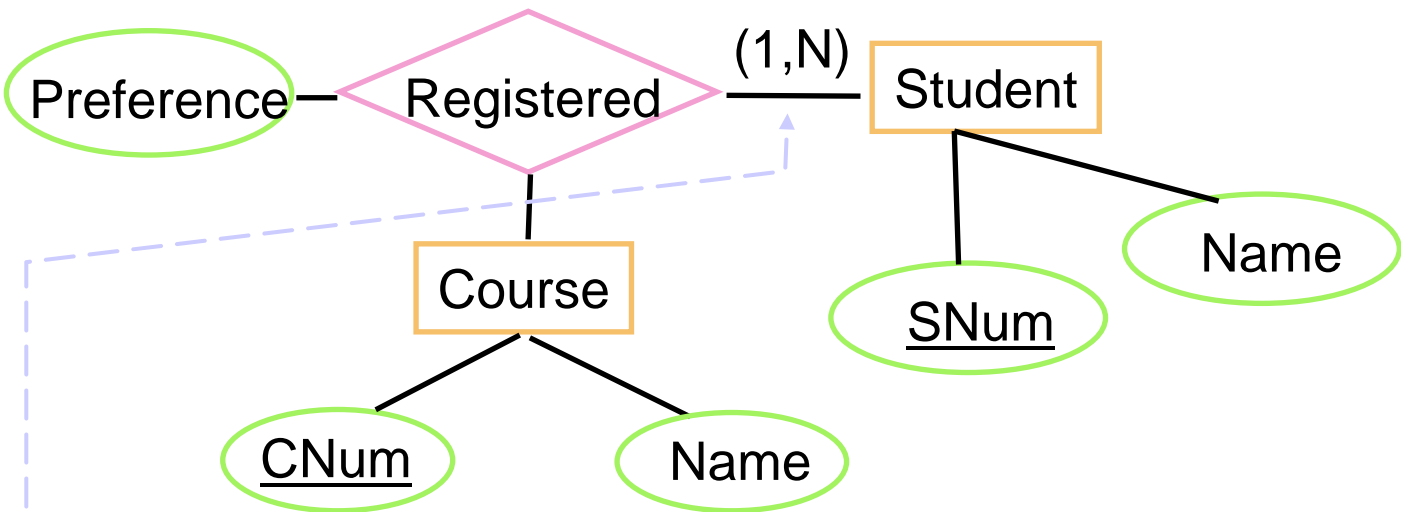

| | | | | |
|--------------------|-----|----|-----|-----------|
| <u>TD1Category</u> | CPP | EI | EHT | IncomeTax |
|--------------------|-----|----|-----|-----------|

...continued

- Otherwise: relationship set $R \rightarrow$ table R
- Columns of table R include:
 - attributes of the relationship set
 - primary key attributes of each component entity set
- Primary key of table R :
 - if some component entity set E has the general cardinality constraint $(0,1)$, choose the primary key attributes for E
 - otherwise, choose the primary key attributes of each component entity

...continued

- **E.g.**

Student

| | |
|-------------|------|
| <u>SNum</u> | Name |
|-------------|------|

Course

| | |
|-------------|------|
| <u>CNum</u> | Name |
|-------------|------|

Registered

| | | |
|-------------|-------------|------------|
| <u>SNum</u> | <u>CNum</u> | Preference |
|-------------|-------------|------------|

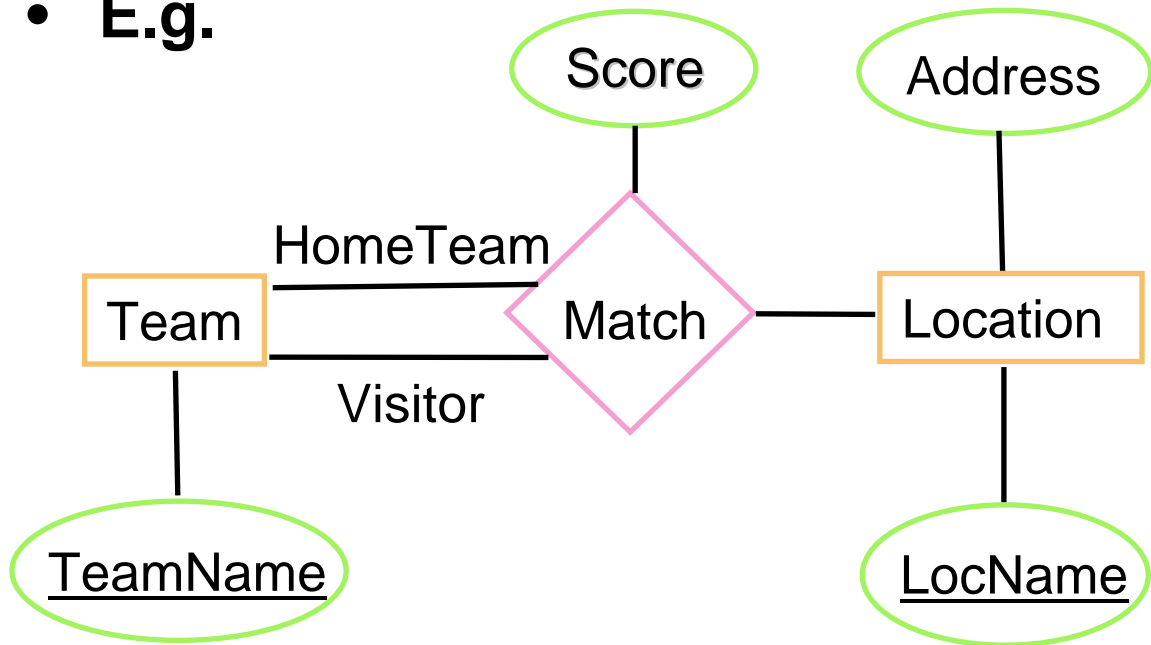

- Cardinality (1,N):

- Cardinality (0,1):

| | | |
|-------------|------|------------|
| <u>SNum</u> | CNum | Preference |
|-------------|------|------------|

...continued

- **E.g.**

Location

| | |
|----------------|---------|
| <u>LocName</u> | Address |
|----------------|---------|

Team

| |
|-----------------|
| <u>TeamName</u> |
|-----------------|

Match

| | | | |
|---------------------|------------------------|----------------|-------|
| <u>HomeTeamName</u> | <u>VisitorTeamName</u> | <u>LocName</u> | Score |
|---------------------|------------------------|----------------|-------|

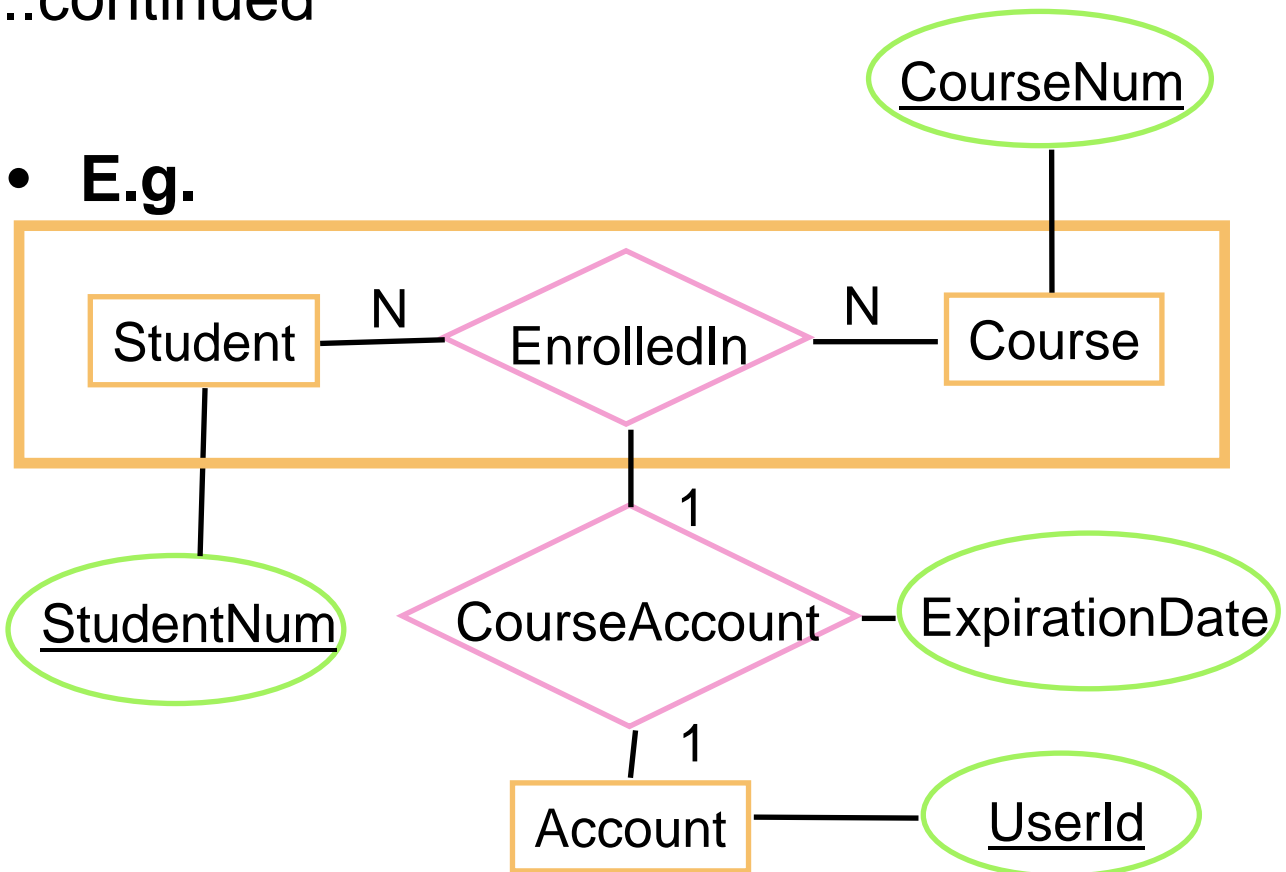

- Note that the role name of a component entity set is prepended to its primary key attributes

Representing aggregation

- Tabular representation for aggregation of relationship set R = tabular representation for relationship set R
- To represent relationship set involving aggregation of R , treat the aggregation like an entity set whose primary key = primary key of the table for R

...continued

- **E.g.**

Student

| |
|-------------------|
| <u>StudentNum</u> |
|-------------------|

Course

| |
|------------------|
| <u>CourseNum</u> |
|------------------|

Account

| |
|---------------|
| <u>UserId</u> |
|---------------|

EnrolledIn

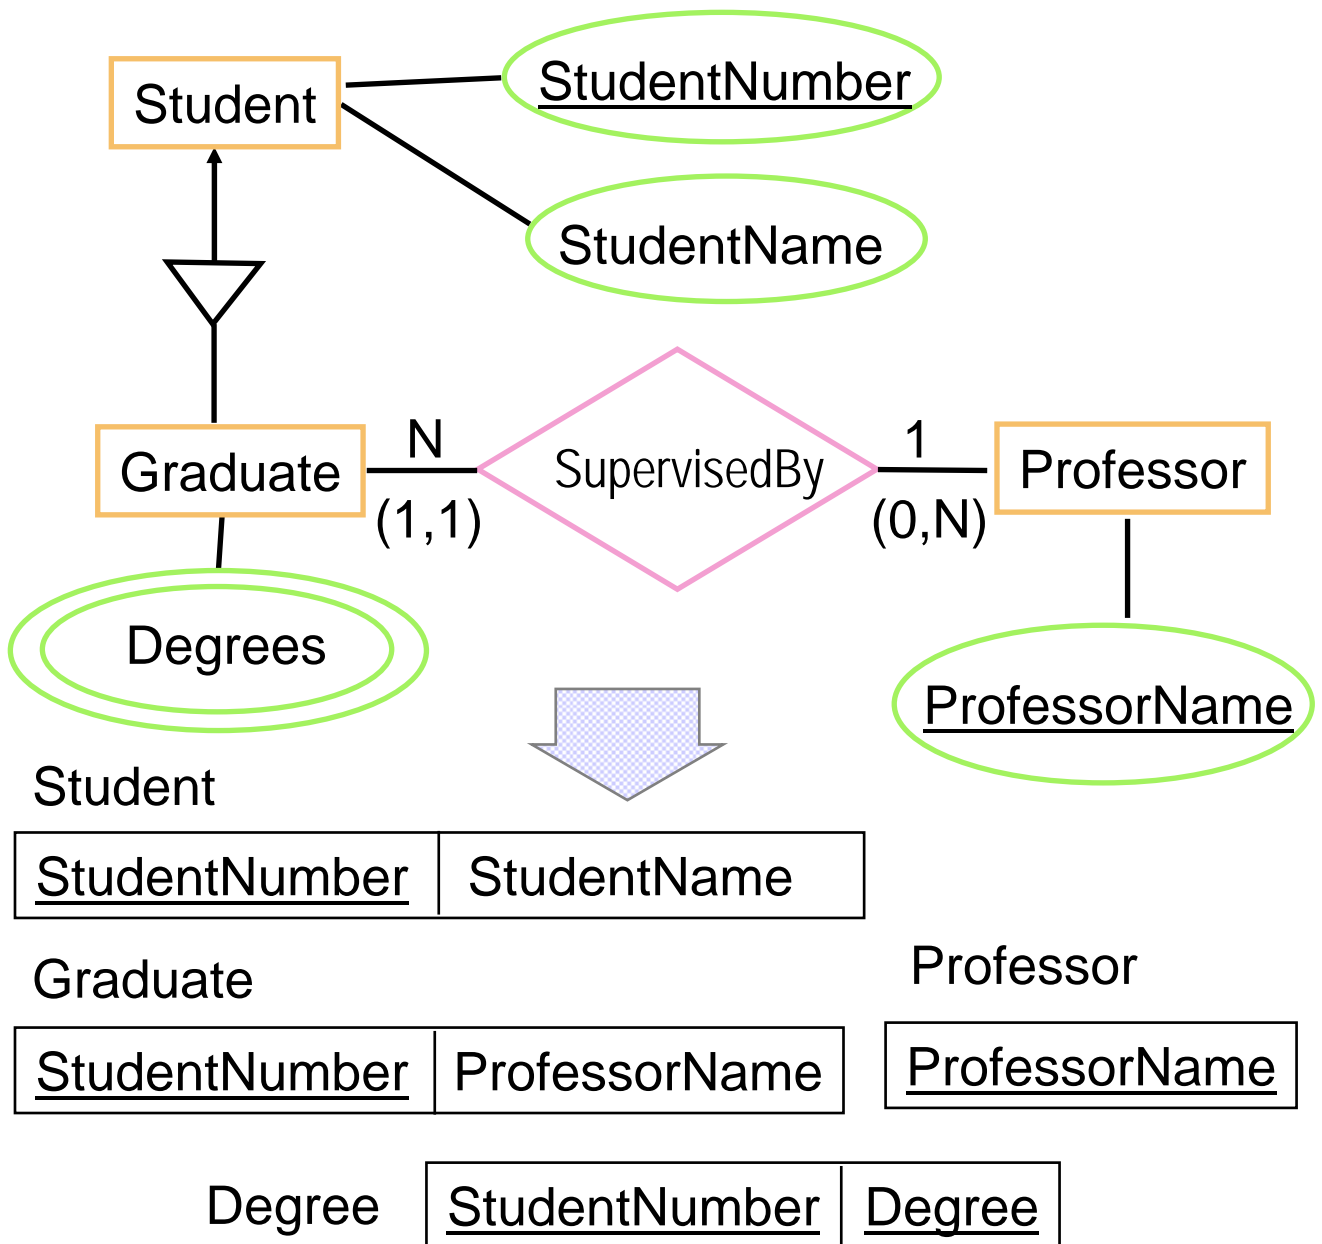

| | |
|-------------------|------------------|
| <u>StudentNum</u> | <u>CourseNum</u> |
|-------------------|------------------|

CourseAccount

| | | | |
|---------------|------------|-----------|----------------|
| <u>UserId</u> | StudentNum | CourseNum | ExpirationDate |
|---------------|------------|-----------|----------------|

Representing specialization

- Create specialized table with primary attribute of higher-level entity, plus attributes as usual

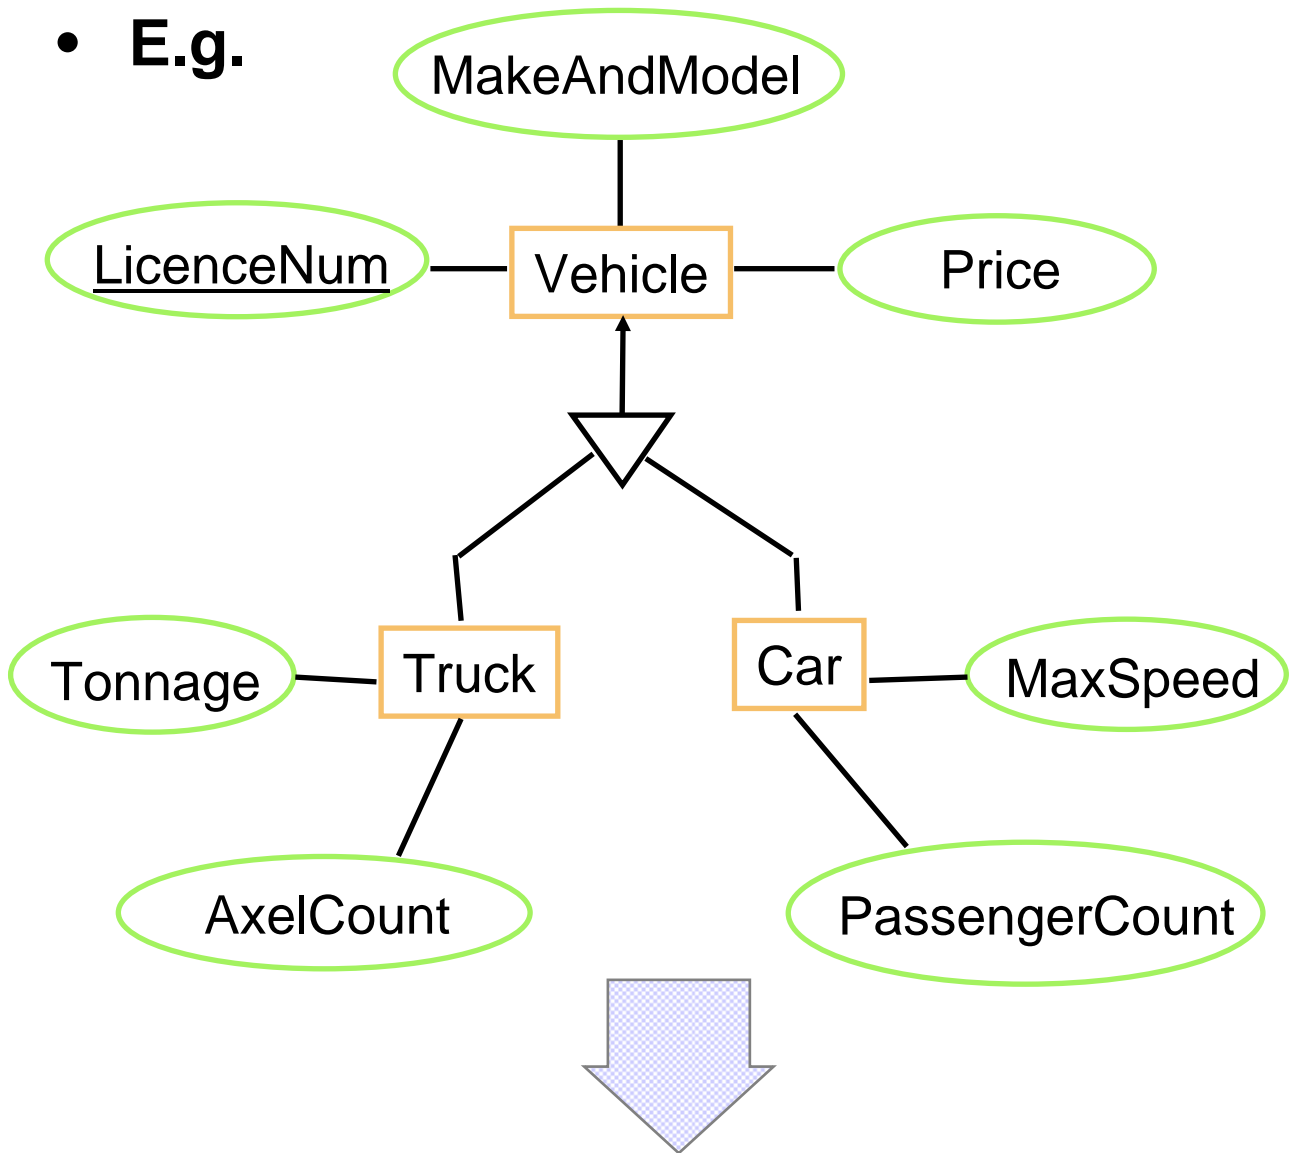

Representing generalization

- Create a table for each lower-level entity set only
- Columns of new tables should include:
 - Attributes of lower level entity set
 - Attributes of the superset
- The higher-level entity set can be defined as a view on the tables for the lower-level entity sets

...continued

- **E.g.**

Truck

| | | | | |
|-------------------|--------------|-------|---------|-----------|
| <u>LicenceNum</u> | MakeAndModel | Price | Tonnage | AxelCount |
|-------------------|--------------|-------|---------|-----------|

Car

| | | | | |
|-------------------|--------------|-------|----------|------------|
| <u>LicenceNum</u> | MakeAndModel | Price | MaxSpeed | P'gerCount |
|-------------------|--------------|-------|----------|------------|
